

Stablecoin Factory

A faster way to launch a simple stablecoin. Everything on one page: who the customer is, why they buy, and what the product does — and does not do.

Owner: Commercial · Confidential

THE CUSTOMER IN ONE LINE

A builder, technical team or innovation team with a **concrete stablecoin or tokenised-asset use case, looking for a fast, self-serve route from concept to live deployment.**

THE BUYER

Builder · CTO · innovation lead

With a concrete use case and a mandate to ship.

THE CYCLE

Weeks to a quarter

Self-serve deployment, not an institutional programme.

THE LINE

Aryze is infrastructure

Never the issuer, never the regulated operator.

Part 1 — The customer

Definition

Stablecoin Factory is **infrastructure, not regulated operation**. The customer remains the issuer; Aryze delivers the deployment layer. If the customer needs a full institutional operating model from day one — settlement, ramps, treasury, multi-currency, governance — that is Digital Cash, not Stablecoin Factory.

This customer is not after a demo. They have a use case they want to test in practice, and they want to reach live deployment without burning months on a custom build or enterprise contracts.

Strongest customer types, in order

1 Technical founders

With a stablecoin or RWA idea — deploying to validate before raising or scaling.

2 Fintech builders

Adding a stablecoin or RWA feature to an existing product.

3 Web3 builders

Who need real infrastructure, not another token template — typically seed to Series A.

4 Innovation, digital-asset & venture teams

Innovation teams inside larger companies testing tokenised use cases before central tech takes over; digital-asset teams at fintechs or financial groups moving a pilot from concept to live; internal venture teams proving a use case before central buy-in; and exploratory operators in regulated spaces, using Factory as a lightweight proof point before considering Digital Cash.

What the customer wants

"Launch a simple stablecoin (or tokenised asset) faster, with less friction."

A practical route from concept to live. They want to test a use case before committing to a broader infrastructure model. They value speed, clarity and real-world learning.

The five pains we solve

- 1. The path from idea to live is too heavy.** Too many technical decisions, components, vendors, legal questions and internal discussions. Teams spend months scoping before testing anything real.
- 2. A custom build costs too much.** 6–12 months and several full-time engineers, with no guarantee the use case validates.
- 3. A fragmented vendor stack.** Wallet, ledger, custody, ramps, compliance — all separate suppliers in a typical DIY deployment. Every integration costs time.
- 4. Enterprise complexity arrives too early.** Teams do not need a full institutional layer to test a use case — but the market pushes them toward it anyway.

5. No clear starting point. Without a visible deployment flow, stablecoin and RWA projects sit in concept mode for quarters.

Fit & walk-away signals

Strong-fit signals — the more that are present, the better the fit:

The use case fits in one sentence

A technical team can evaluate via sandbox and documentation

The path to live has a time horizon — weeks to a quarter

Speed and usability are prioritised over enterprise features

The issuer model is clear — the customer or their parent entity holds the licence

Self-serve fits — they do not want a six-month enterprise engagement

A later move up to Digital Cash is acceptable, not a deal-breaker

The motion fit is identified — own programme, partner-led or white-label

Walk-away signals — when these are true, it is not a fit:

Needs the full institutional operating layer from day one — route to Digital Cash

No concrete use case — only "exploring stablecoins / RWAs"

No technical team to use the sandbox

Expects Aryze to be the issuer or regulated operator — that is not the product

Wants a custom-built enterprise programme from day one

Pure research mode, without an execution path or budget

Expects a custom contract and a long legal process — that is Digital Cash, not Factory

The use case requires a licence the customer does not hold — Aryze does not deliver licences

Best-fit company profile

- Has a **concrete stablecoin or RWA use case** — not "we are exploring stablecoins"
- Has a technical team that can use a self-serve flow
- Values speed and usability over enterprise features
- Wants to test and learn before committing to a deeper infrastructure model

- Can evaluate the product technically — sandbox, documentation, deployment flow
- Understands that Aryze is infrastructure and the customer is issuer
- Has a path to live they can act on within weeks to a quarter

Buying triggers

- The use case is validated — no longer "considering" — but the path to live is unclear
- A custom build is too heavy — the team has estimated the months it would take
- The current vendor stack is fragmented — too many suppliers, decisions and integrations
- The business is pushing for speed — the market window is now, not in 12 months
- The team expects to grow into Digital Cash later — but not today
- Investor pressure — Series A/B investors want a live deployment before the next round
- An internal venture pilot — central buy-in depends on showing an actual deployment, not a deck

Three go-to-market motions — the buyer changes per motion

MOTION	BUYER	WHAT THEY WANT	THE CONVERSATION
Own Programme Deployment	Founder, CTO, Head of Product	Speed to live, low custom build, keep brand and control	Tech walkthrough → sandbox → scope deployment
Partner-Led Distribution	Distribution / BD / platform lead	Deliver tokenised products through their partner network	Commercial framing first → then scope partner onboarding
White-Label Enablement	Platform or product lead, commercial lead	A productised infrastructure layer to re-sell or embed under their own brand	Longer commercial cycle → contract detail + branding

The motion is settled before the deal is scoped. Economics, contracting and integration depth differ substantially across the three.

Who buys

Primary (technically led): Founder / co-founder (especially seed-Series A), CTO / VP Engineering, technical lead or principal architect, Head of Innovation.

Secondary (product-led): product lead, Head of Digital Assets, platform lead for partner and white-label motions.

The buying committee is smaller and more technical than Digital Cash — typically 2–4 people, and without treasury, MLRO, compliance or general counsel, because Factory does not touch the institutional setup. Each role weighs the product differently: a CTO focuses on the technical walkthrough and sandbox; a founder focuses on time-to-live and deployment cases; an innovation lead focuses on the pilot framework and success criteria.

Qualification questions for the first call

1. What is the concrete use case — stablecoin (what kind), tokenised RWA, settlement asset, internal value transfer?
2. Where are you today — concept, prototype, ready to deploy, or live elsewhere?
3. What is the trigger now — why this quarter and not next year?
4. Who is on the team — founder + tech, product, internal venture, innovation?
5. Who is the issuer — you, or a partner / parent licensed entity?
6. Which motion fits — own programme, partner-led, or white-label?
7. What is the time horizon — weeks, a quarter, or longer?
8. Have you evaluated other deployment paths — custom build, other vendors?

The single most important qualifier is whether the customer needs simple deployment or full institutional operation. Simple deployment is Stablecoin Factory. Full institutional operation is Digital Cash. The two are not interchangeable, and the distinction determines which product applies.

How we position it

"A faster way to launch a simple stablecoin or tokenised asset — self-serve deployment infrastructure that gets you from concept to live without enterprise complexity on day one."

The positioning stays close to speed, simplicity and the deployment path. There is no abstract Web3 story — this customer needs to get from concept to live, not a new financial paradigm.

Market context

- **The EU MiCA framework is mature** — stablecoin deployment under EU regulation is possible, but teams need infrastructure that respects the rules without becoming enterprise-complex on day one
- **US stablecoin legislation** is pushing US fintechs to clarify their stablecoin strategy
- **The RWA segment is growing fast** — tokenised T-bills, real estate and private credit attract capital; builders want infrastructure that supports RWA deployment without building everything themselves
- **Web3 builders are moving toward real infrastructure** after years of disappointing token projects
- **The enterprise pilot phase is over** — large banks (BBVA, Santander, JPM, Citi) have run pilots; the mid-market follows
- **Self-serve, AI-assisted tooling is the expectation** — not custom code from 2018

The competitive field

COMPETITOR	POSITION
Fireblocks	Dominant custody + stablecoin tooling, enterprise-focused. Often too heavy and expensive for light deployment cases.
Circle	USDC issuer + stablecoin platform. Competitor on USDC, potential partner via their API.
Brale	Issuer-as-a-service, US-focused. Direct competitor on self-serve stablecoin issuance.

Bridge (Stripe)	Stablecoin payment infrastructure — more payment rail than deployment layer.
M^0	Programmable stablecoin protocol — more protocol than deployment tooling.
Stably	Issuer-as-a-service, smaller player.
Tokeny / Securitize	RWA-focused tokenisation platforms — stronger on RWA than stablecoins.

Factory's room in this field is the job the customer has that these vendors do not solve today — typically self-serve speed and the clear path up to Digital Cash when the use case grows. The product anchors in stablecoins; RWA is a broader application, and RWA-specific capabilities are confirmed against the product rather than assumed.

Part 2 — The value proposition

The customer's jobs

FUNCTIONAL

Deploy a stablecoin or tokenised asset from concept to live; test the use case in practice before deeper commitment; validate product-market fit; iterate on design and parameters (token model, supply mechanism, custody, networks); integrate the deployment with their own product or partner platform; keep governance and operational control.

PROFESSIONAL

Show investors, board and partners that the use case runs live; demonstrate technical maturity; differentiate from competitors still in concept mode.

EMOTIONAL

The feeling of moving from "we are exploring" to "we are live"; trust that the infrastructure layer is not a black box; pride in a deployment that did not take six months of custom build; the sense that it is still the customer's product, not Aryze's.

From pain to relief

Time to live — the path from idea to live is too heavy; a custom build costs months before there is anything to show; enterprise sales cycles are too long to validate a use case in time.

Weeks, not 6–12 months — a self-serve flow: weeks to a quarter instead of 6–12 months. Pre-built infrastructure — no custom build from scratch.

Cost — custom infrastructure is expensive (engineers, a vendor stack, integration time); enterprise vendors price for institutional use, not exploratory deployment.

One layer, self-serve pricing — one coherent infrastructure layer replaces the fragmented vendor stack. Self-serve pricing instead of an enterprise contract. Less internal engineering burden.

Complexity — a fragmented stack (wallet, ledger, custody, ramps, compliance) all separate; technical decisions are hard without domain experience; compliance, legal and tech each take their own time.

One deployment flow — one deployment flow replaces many vendors. A pre-validated technical model means fewer custom decisions. Documentation and sandbox let the team learn on their own.

Risk — time and capital invested without knowing whether the use case works; technical choices can prove wrong and force redeployment; the regulatory landscape shifts (MiCA, US legislation).

Test and learn first — test and learn before deeper commitment. The migration path to Digital Cash means no rebuild when the use case grows. The customer stays issuer — a clean legal position.

Outcome — without a clear starting point the project sits in concept mode and the team loses investor and internal momentum; without a path to bigger infrastructure they cannot answer "what happens if it grows".

Out of concept mode — a visible deployment path moves the project out of concept mode, and gives a clear line to investors and the board: "we are live on Aryze."

The pains

TYPE	PAIN
Time to live	The path from idea to live is too heavy — too many decisions, vendors and internal alignment. A custom build costs months before there is anything to show. Enterprise sales cycles are too long to validate a use case in time.

Cost	Custom infrastructure is expensive — engineers, a vendor stack and integration time. Enterprise vendors price for institutional use, not exploratory deployment.
Complexity	A fragmented stack: wallet, ledger, custody, ramps, compliance — all separate. Technical decisions are hard without domain experience. Compliance, legal and tech each take their own time, with no clear order.
Risk	Time and capital invested without knowing whether the use case works. Technical choices can prove wrong and force redeployment. The regulatory landscape shifts (MiCA, US legislation).
Outcome	Without a clear starting point the project sits in concept mode, and the team loses investor and internal momentum. Without a path to bigger infrastructure they cannot answer "what happens if it grows".

The gains

LEVEL	GAIN
Required	A fast, clear route from concept to live. Enough customisation to match the use case. A self-serve experience without an enterprise sales cycle. A clear issuer/operator model — the customer owns it.
Expected	Sandbox and documentation the technical team can evaluate alone. Low-friction issuance. Branding control. A modern, assisted deployment flow.
Desired	A path up to Digital Cash if the use case grows institutional. Real-world learning. Partner and white-label options.
Unexpected	Assisted setup that cuts manual work. A migration path that is real, not a marketing claim. Credibility from being on Aryze infrastructure — a Copenhagen fintech with Mastercard rails, not a token experiment.

What we deliver

- **The Stablecoin Factory deployment layer** — self-serve infrastructure for simple stablecoin and tokenised-asset deployment
- **A self-serve deployment flow** — concept to live without enterprise complexity on day one
- **Sandbox and documentation** — the technical team evaluates before any commercial commitment

- **Three commercial motions** — own programme, partner-led distribution, white-label enablement
- **A path up to Digital Cash** when the use case outgrows the deployment layer
- **Issuer preservation** — the customer remains issuer under their own licence

How that relieves the pains

PAIN	RELIEF
Time to live	Self-serve flow: weeks to a quarter instead of 6-12 months. Pre-built infrastructure — no custom build from scratch.
Cost	One coherent infrastructure layer replaces the fragmented vendor stack. Self-serve pricing instead of an enterprise contract. Less internal engineering burden.
Complexity	One deployment flow replaces many vendors. A pre-validated technical model means fewer custom decisions. Documentation and sandbox let the team learn on their own.
Risk	Test and learn before deeper commitment. The migration path to Digital Cash means no rebuild when the use case grows. The customer stays issuer — a clean legal position.
Outcome	A visible deployment path moves the project out of concept mode, and gives a clear line to investors and the board: "we are live on Aryze."

Factory vs Digital Cash — two distinct products

QUESTION	STABLECOIN FACTORY	DIGITAL CASH
Who is issuer?	The customer	The customer
Who operates?	The customer (self-serve)	The customer (institutional scale)
Aryze's role	Deployment infrastructure	Operating infrastructure
Sold on	Speed, simplicity, deployment path	Control, credibility, infrastructure depth
Sales cycle	Weeks to a quarter	6-18 months

Buyer

Founder, CTO, product or
innovation lead

Executive sponsor + treasury,
MLRO, GC, risk

Factory is not "lightweight Digital Cash", and Digital Cash is not "scaled-up Factory". They are different products for different customers through different motions, and the distinction holds throughout.

Part 3 — The product

Overview

Stablecoin Factory is built for teams that want to move from concept to live deployment without a long enterprise process, a large custom build, or the full complexity of institutional digital-cash infrastructure. It helps teams launch, test and learn faster — a practical way to start before they know whether the use case needs a deeper operating model.

Two distinctions hold throughout: Factory is simple deployment, and Digital Cash is institutional operation. And Factory is infrastructure — Aryze does not become issuer or regulated operator; that role stays with the customer or a partner / parent licensed entity.

A self-serve infrastructure layer that lets teams launch a simple stablecoin or tokenised asset without starting with enterprise complexity on day one.

What's in the box

In the box — confirmed

- ✓ **No-code token creation** — pick a name, ticker and image; Aryze handles the contract, deploy and verification.
- ✓ **Live in about 60 seconds** — connect a wallet, complete a short form, confirm, and the token is on-chain.
- ✓ **An issuance path** for a simple stablecoin or tokenised asset.
- ✓ **Multi-chain on EVM networks** — Ethereum, Arbitrum, Polygon, BNB Chain and more, with the same token address across chains.
- ✓ **LayerZero V2, native** — omnichain messaging wired in, so holders can bridge the token across supported networks from day one.
- ✓ **Security by default** — pausing, allow-lists and audited upgrades; production-grade and tested on mainnet.
- ✓ **Token management** — issue on demand; send, receive and swap; allow-list trusted users; pause transfers; upgrade securely over time.
- ✓ **Documentation and sandbox** for technical evaluation without a sales process.
- ✓ **Three go-to-market motions** (below).

Deliberately not in the box

- **Aryze does not become the issuer** — the customer remains issuer under their own licence (or a partner / parent licensed entity).
- **Aryze does not become the regulated operator** — the customer operates.
- **Factory is not Digital Cash** — full institutional operation routes to Digital Cash.
- **No custom enterprise programmes from day one.**
- **RWA capabilities beyond the one-pagers** — the product anchors in stablecoins, and RWA capabilities are confirmed against the product rather than assumed.
- **Specific networks, jurisdictions and custody partners** — confirmed per deal against the product.
- **The Factory → Digital Cash migration** — a path, not a productised step; the technical migration depends on the use case.
- **Licence delivery** — Aryze does not deliver the licence.

- ✓ **A path up to Digital Cash** if the use case scales, with the issuer model staying with the customer.

The three commercial motions

MOTION	WHAT IT IS	BUYER	CYCLE
Own Programme Deployment	The customer deploys their own stablecoin/RWA programme on Aryze infrastructure. The customer is issuer; Aryze delivers the deployment layer.	Founder, CTO, Head of Product, technical lead	Weeks to a quarter
Partner-Led Distribution	The customer is a distributor, integrator or platform reaching end users through partners, delivering tokenised products through their network.	Head of Distribution / BD, platform lead, Head of Partnerships	One to two quarters
White-Label Enablement	A partner takes Factory under their own brand — a productised infrastructure layer to re-sell or embed.	Platform lead, Head of Product, commercial lead	Two quarters or more

The motion is settled before the deal is scoped — economics, contracting and integration depth differ substantially across the three.

How it is sold

A product-led and ecosystem-led motion — different from both Pay by Bank (commercial merchant motion) and Digital Cash (enterprise institutional motion). Channels: the self-serve product funnel, developer communities, digital-asset events (Token2049, Permissionless, EthCC, RWA events), technical walkthroughs and demos, founder-led conversations, stablecoin/RWA content, and partner channels for the partner-led and white-label motions.

The typical path: inbound or a warm introduction → a qualifying call (use case, motion fit, technical maturity) → technical walkthrough or sandbox access → solution scoping → commercial framing per motion → deployment → and, when relevant, the path to scale into Digital Cash.

Pricing

Self-serve token creation is free to use. Beyond that, pricing varies per motion — own programme, partner-led and white-label have different economics, commitments and success criteria — and follows the motion fit and scope rather than a quote up front.
